Nuclear magnetic resonance (NMR) is a physical phenomenon in which nuclei in a strong constant magnetic field are perturbed by a weak oscillating magnetic field (in the near field) and respond by producing an electromagnetic signal with a frequency characteristic of the magnetic field at the nucleus.

Electron nuclear double resonance is a magnetic resonance technique for elucidating the molecular and electronic structure of paramagnetic species. The technique was first introduced to resolve interactions in electron paramagnetic resonance spectra. It is currently practiced in a variety of modalities, mainly in the areas of biophysics and heterogeneous catalysis.

Electron nuclear double resonance - Wikipedia

Nuclear magnetic resonance and electron paramagnetic resonance (and respectively) are powerful experimental probes of the atomic-scale structure of glass. This chapter provides a practical introduction to the current state of the art of these methods in glass research, and is intended to provide researchers with the basic knowledge needed to apply and interpret the results of these methods.

Nuclear Magnetic Resonance and Electron Paramagnetic ...

This process is called Nuclear Magnetic Resonance (NMR). A magnetic dipole moment (usually just called "magnetic moment") in a magnetic field will have a potential energy related to its orientation with respect to that field. Note that the electron spin magnetic moment is opposite to the electron spin while the proton spin magnetic

Nuclear Magnetic Resonance - HyperPhysics Concepts

Nuclear magnetic resonance (NMR) is a physical process in which nuclei in a magnetic field absorb and reemit electromagnetic radiation. Analysis of NMR spectra allows the determination of polymer composition, and the distribution of monomer units can be deduced from the diad and triad sequences by NMR spectral analysis.

Driving an NMR and detecting its effect on an ESR is known as ENDOR (electron-nuclear double resonance), whereas driving an ESR to increase a nuclear magnetization, observed by NMR, is called DNP (dynamic nuclear polarization). Electron-nuclear double resonance is mainly used in making accurate measurements of hyperfine and superhyperfine splittings for detailed mapping of electron-spin densities.

In physics, biology and chemistry, electron magnetic resonance (EMR) is an interdisciplinary field with several forms: electron paramagnetic resonance (EPR), electron spin resonance (ESR) and electron cyclotron resonance (ECR).

Electron paramagnetic resonance (EPR) or electron spin resonance (ESR) spectroscopy is a method for studying materials with unpaired electrons. The basic concepts of EPR are analogous to those of nuclear magnetic resonance (NMR), but it is electron spins that are excited instead of the spins of atomic nuclei. EPR spectroscopy is particularly useful for studying metal complexes or organic radicals.

Principles of nuclear magnetic resonance (NMR) When a nucleus that possesses a magnetic moment (such as a hydrogen nucleus ^1H , or carbon nucleus ^{13}C) is placed in a strong magnetic field, it will begin to precess, like a spinning top. What we can learn from NMR spectra

Relaxation Effects in Nuclear Magnetic Resonance Absorption

EMR stands for electron magnetic resonance. EMR is very similar to the two other resonance techniques that take place here at the lab: nuclear magnetic resonance (NMR) and ion cyclotron resonance (ICR). The big difference is that EMR looks at electrons rather than nuclei (which is the case in NMR) or ions (in the case of ICR).
